WORKING CATTLE WITH SAFETY IN MIND

February 2015

*F. David Kirkpatrick, Extension Beef Cattle Specialist
Fred M. Hopkins, Professor Emeritus, Animal Science and
College of Veterinary Medicine*

There are many reasons cattle react the way they do when trying to get them up at cattle working time. Many of their reactions are a result of their innate characteristics. Understanding these characteristics and how animals respond to different situations can make cattle handling a safe and less stressful event. Decreasing stress and excitability in both the cattle and cattle handler makes the process safer for both parties. Many accidents happen as a result of people not understanding animal behavior and wanting to get the job done in a hurry.

Vision:

Cattle have panoramic vision in excess of 300 degrees, which means they can see in all directions except for directly behind themselves. In contrast, a human's vision is roughly 180 degrees. Approaching cattle from directly behind can startle them and be dangerous to the handler.

Also, cattle have poor depth perception. Their ability to perceive ground depth while moving is very limited. Because of this trait, they have to stop and lower their heads to focus. Unfamiliar objects and shadows on the ground cause animals to balk when entering or moving through the chute. Due to the limitation in vertical vision and lack of ability to focus, a shadow on the ground can appear to be a large ditch.

Cattle are sensitive to light in a different way than humans, and they move more freely from a dimly illuminated area to a more lighted area if the light is not glaring in their eyes. This is why it is difficult to get them to move into a dark chute from a sunny outdoor crowding pen. If working cattle at night, frosted lamps need to be used in order to eliminate glare in the cattle's eyes.

Hearing:

Cattle hear differently than humans. They can hear both lower volume and higher frequency sounds better than humans but cannot pinpoint the source as well as humans. Loud sounds scare them very easily. Because of their poor depth perception, excessive screaming and hollering can agitate them and cause them to move away from the source and crash into fences or other objects, including people. Be extremely careful of cattle with sight problems (such as cancer eye), as they rely on hearing to a greater extent and may overreact to sounds.

Flight Zone or Distance:

Just like people, cattle have a comfort zone. Their flight zone is measured by how closely you can approach them before they move. When you enter an animal's flight zone, it will start to move. If approaching cattle from the front, they will turn around and move away from you. If approaching them from the rear, they will turn to look at you and move forward. Depending on their temperament, the speed at which they move will vary. Wild cattle or those that have had bad experiences with cattle handling will have larger flight zones than docile cattle and will not allow a person to get near them before moving. Calmer cattle will allow a person to get closer to them before they start to move.

Familiarity with the cattle handler will also affect the size of the flight zone. The cattle will be more apprehensive with persons who are unfamiliar.

Herd Instinct:

Cattle are prey animals and feel comfortable and safe in a group. This instinct causes them to want to be in a group and follow other animals' movement in that group. Being alone may cause them to experience heightened anxiety, fearfulness and willingness to fight back in a situation that a human might not perceive as dangerous. When a bull is separated from the herd, it can become very stressed, agitated and aggressive. It is often much easier to allow one or two additional animals to go with a bull when it is separated.

Maternal Instinct:

Cows have a defensive instinct to protect their young from danger. A cow or heifer's behavior can become very unpredictable at or after calving. A docile animal can become aggressive and charge when being separated from their young. A cow is often aggressive just after calving and is not to be trusted. Usually the younger the calf, the more dangerous the mother. Always keep the calf and some barrier between yourself and its mother when ear tagging or conducting any other procedure with newborn calves.

Territorial:

Animals are attached to their own territory and are comfortable in that area. Changing environments or location alters their comfort level and can lead to changes in temperament. They may become very tentative when exposed to strange surroundings. Also, in a new environment they sometimes try to re-establish a new pecking order. A single animal moved to a foreign environment may become overly agitated and aggressive. It is best to provide that single animal with a companion animal to overcome stress and excitement.
