Growers who follow soil test recommendations can expect higher fertilizer efficiency, more balanced nutrient levels for crops and optimum benefits from their lime and fertilizer investments. Thus, soil testing should be the first step in planning a sound fertilization program. With a soil test, the guesswork of knowing how much lime and fertilizer to apply is eliminated.

**The Concept of Soil Testing**

When you submit a sample to the University of Tennessee Soil, Plant and Pest Center, modern chemical analyses are combined with up-to-date research to make each lime and fertilizer recommendation. Levels of Mehlich 1 extractable nutrients present in the soil are determined in the laboratory, while nutrient needs and fertilizer responses of the major soil types across the state are determined at the AgResearch and Education Centers. As a result, the university’s soil testing program is geared to the crops and soils in Tennessee and provides a vehicle for delivering the latest scientific information to individual growers.

**Information Sheets and Sample Boxes**

Information sheets, soil sample boxes, and sampling instructions can be obtained from your local UT Extension office or online at ag.tennessee.edu/spp. These materials provide necessary information and guidelines for collecting and mailing samples to the laboratory.

When filling out information sheets please be as complete as possible. For each sample ID listed in the left column of the form, you may request up to four recommendations. Use the UT crop codes listed at the online site to determine the appropriate codes to list under the “Crop Code(s)” column. If your crop is not coded or if you are uncertain about which code to choose, list the name of the crop in place of a code.

Soil sample boxes should be labeled properly with identifications corresponding to those shown in the sample ID box on information sheets. Please be sure to put your name or company name on all boxes. Please keep sample IDs simple and legible. Last names, numbers and simple descriptors are common. Examples are Smith 1, Garden, NW corner.

**The Sampling Area**

Soil test results are no better than the sample collected. Thus, each soil sample submitted to the laboratory should be representative of the area for which fertilizer recommendations are to be made. A composite sample consisting of small portions of soil taken from approximately 20 locations should be collected. For field crops, soil portions should be taken from an area not to exceed 10 acres (Figure 1). For lawns and gardens, soil portions should be collected at random from eight to 10 locations. Areas of contrasting soils, problem spots, areas under different management within the same field, or portions of fields where crop response is significantly different should be sampled separately, provided the area can be fertilized separately. For example, if a small portion of a larger field had been used to produce a crop with vastly different fertility, like tobacco, then it should be sampled separately. Other examples would include old home sites, areas of animal confinement or where fence rows were removed to make a larger field.

---

**Figure 1. Sampling pattern for collecting a representative soil sample.**
Sampling Tools and Depths to Sample

Several types of tools can be used for collecting soil samples. One is the soil tube or probe. A uniform portion of soil is collected rapidly and accurately by pushing the tube into the ground to the desired depth and removing a soil core.

The most common tool used is a shovel or spade. With this tool, a uniform portion of soil is collected by first making a V-shaped cut into the soil to the depth of sampling. Next, a 1-inch thick vertical slice of soil to the same depth is removed from the smoothest side of the cut (Figure 2). Then, a 1-inch strip of soil the length of the slice is removed, as indicated in Figure 3. If other tools are used for sampling (garden trowel, auger, etc.), make sure that a uniform amount of soil is collected to the desired depth from a sufficient number of sites within the sampling area.

Remove organic debris, rocks and trash from the soil surface before collecting the sample. For determination of pH, P, K, Ca, Mg, micronutrients and organic matter, take soil samples to a depth of 6 inches. For determination of soluble salts, sample within the rooting zone of the affected crop or the expected rooting zone if the sample is taken prior to crop establishment. For the corn pre-sidedress nitrate-nitrogen test, collect samples to a depth of 12 inches.

Soil portions for each composite sample should be placed in a clean container (not zinc-coated if determining Zn) and mixed thoroughly. Then, remove enough soil to fill a sample box (Figure 4). When sampling for nitrate-nitrogen, the sample should be air-dried thoroughly within 36 hours to obtain the best results.

When to Sample

Although soils can be tested at any time during the year, fall is a very desirable time. Fields are usually drier and more accessible, and the laboratory is less rushed than in the spring. Also, testing in the fall allows recommended rates of lime, phosphate and potash to be applied well in advance of spring planting. By sampling at approximately the same time each year, there is less error when comparing soil test results with previous results from the same field.

Soils should be dry enough to till when sampling. If wet samples are collected, they should be air-dried before being packaged and mailed. Wet samples are difficult to handle, more subject to being lost during mailing and greatly delay laboratory testing. Wet samples cannot be analyzed for nitrate-nitrogen.

How Often to Test Soils

The following general guidelines may be used to determine how often soils should be tested. However, the frequency can vary depending on cropping intensities, soil types, fertilization rates, tillage methods, weather conditions and new research findings.

1. Continuous Row Crops (conventional) — every two to three years.
2. Double-cropping Systems — every two years.
3. Continuous No-till Soybeans (only) — every three to five years.
4. Continuous No-till Corn or Cotton — every two years.
5. Hay Systems — every two years.
6. High-value Cash Crops (tobacco, vegetables) — annually.
7. Lawns, Gardens and Pasture Crops — every three to five years.
8. Any time a nutrient problem is suspected.
9. At the beginning of a different cropping rotation.

Soil, Plant and Pest Center lime recommendations should be applied once, but, unless otherwise specified in the recommendation, fertilizer recommendations should be followed until the next soil sampling date.

Laboratory Tests and Fees

The University of Tennessee Soil, Plant and Pest Center is located at the Ellington Agricultural Center in Nashville, TN. It is equipped for routine soil analysis to make lime and fertilizer recommendations and offers its services to all Tennesseans. Currently, the laboratory uses the Mehlich No. 1 (Double Acid) extractant for nutrient determinations and a Buffer for determining lime requirements.

For a full list of analyses and prices, please check online at ag.tennessee.edu/spp.
Routine tests for other nutrients are not offered for two reasons: First, UT research and field trials may not have indicated a crop response to their use, and, second, recommendations are made more accurately based on soil conditions and specific crop needs (nitrogen, molybdenum).

### Selecting the Proper Tests

Most crop fertilization problems in Tennessee are associated with the lack of, and improper use of, nitrogen, phosphorus, potassium and lime. Therefore, the greatest need for soil test information arises from these four variables. The need for secondary and micronutrient soil tests is much less, since research and demonstrations indicate that responses are limited to certain crops and soil conditions (see SP 645). Situations where the various soil tests are most likely needed are shown in Table 1. Tests desired for each sample must be indicated on the information sheet.

### Computer Soil Test Report

Results of each soil test and corresponding recommendations are printed by computer and mailed and/or mailed to the grower. In addition, a copy of each report is retained by the laboratory, and one copy is sent to the grower’s county Extension office.

Each nutrient tested is reported in pounds per acre and assigned a soil test rating. The ratings for phosphorus and potassium are low (L), medium (M), high (H) and very high (VH). The secondary and micronutrients tested are rated as either sufficient (S) of deficient (D). Interpretations of ratings are printed on the back of the soil test report form. Some other labs may report nutrients tested in parts per million (ppm). For a 6-inch soil sample this value can be converted to pounds per acre by multiplying by two.

Recommendations for field crops are reported in pounds of plant nutrients and tons of agricultural limestone to apply per acre. For lawns and gardens, recommendations are reported in pounds of actual fertilizer grades and agricultural limestone to apply per 1,000 square feet. Recommendations for flowers and shrubs are reported in pounds per 10 and pounds per 100 square feet, respectively. Growers should keep a file of all soil test reports arranged by fields or areas.

### Pre-sidedress Nitrate-N Soil Test

The laboratory offers a special soil test for nitrate-nitrogen to assist with nitrogen management decisions in corn production systems. Samples are analyzed for nitrate-nitrogen using an ammonium and nitrate analyzer. Submission sheet, institutions and fees are available online at ag.tennessee.edu/spp. One may also look up UT Extension fact sheet, “SP 427: Using Pre-sidedress Nitrate-N Soil Test for Nitrogen Management,” or BESS #105 for detailed information on the PSNT procedures.

### Greenhouse Container Media

For greenhouse or potting media mixes we use a saturated paste extract. To have enough extract, we need 1-half gallon of media. Please look on our website for fees and submission form.
