Eriophyid mite species cause a variety of pouch galls on red, sugar and silver maples. Pouch gall formation, a localized growth reaction of the infested plant, occurs as a result of mite feeding activity. The species of mite can be identified by the specific characteristics of the gall on the host plant.

**Maple Bladder Gall**

Feeding by the maple bladder gall mite, *Vasates quadripedes*, causes a pouch-like growth known as bladder gall on the upper leaf surface of red and silver maples. The galls are variable in shape, rounded or elongated. They are usually crowded and numerous at the base part of the leaf between the larger veins.

The exterior of the galls appears wrinkled and glossy. They change from yellowish green or dark green progressively to pink, brown and finally black. The interior of the gall is hollow. The exit for the new generation of mites is from the underside of the leaf.

**Maple Spindle or Finger Gall**

The spindle or finger gall mite, *Vasates aceriscrumena*, is common on sugar maples. The galls are elongated, pointed or spindle-shaped. They are variable in size up to 0.2 inch in length and tend to crowd at the tip end of the leaf blade. The galls vary from greenish tinged with yellow, to pink to crimson.

The interior of the gall is thin-walled and the exit hole is on the underside of the leaf.

**Life History of Eriophyid Mites**

The mites exit the galls in the fall and migrate to terminal buds of the host tree. The mites enter the buds and overwinter under the bark scales.

In the spring, the mites ride out on the growing leaves. Mite feeding results in the formation of galls. The mites then enter the galls, lay eggs and die. The summer generation of mites occupies the galls during the summer.

**Injury to the Maple Trees**

Heavy mite infestation and gall formation causes leaf discoloration and distortion. Usually the infestation levels do not cause severe stress in the tree.

**Control Measures**

In early spring before leaf buds break, spray bark with a horticultural oil as a dormant application. Some varieties of maples are susceptible to oil injury. Early in the spring when the leaves are about one-fourth expanded, spray with one of the listed insecticides/miticides. Mites are exposed on the leaf surface at this time. Cover the upper and lower leaf surfaces with the spray, and repeat the application in 10 days.
For residential landscape use:
carbaryl (Sevin, carbaryl), insecticidal soap (Safer Insectidal Soap), or horticultural oil (various brand names).

For commercial outdoor use:
See https://tiny.utk.edu/ag/insectandmite.

Always refer to the insecticide label to make sure that the insecticide or miticide can be legally applied on ornamental plants at your site, such as residential landscape or commercial nursery.
